Sponsored by the Naval Oceanographic Office
Purpose

- Determine the impact of bottom type and wind variations on bottom moored mine detection

- Determine the significance of transducer depth on bottom moored mine detection
Navy Relevance

- Littoral engagement
- Mine warfare
- Diesel submarines
- Unmanned Undersea Vehicles (UUVs)
CASS/GRAB

- Comprehensive Acoustic Simulation System (CASS)
- Gaussian Ray Bundle (GRAB) Eigenray model
- Navy standard model for active and passive range dependent acoustic propagation, reverberation and signal excess
- Frequency range 600Hz to 100 kHz
CASS/GRAB Model Description

- The CASS model is the range dependent improvement of the Generic Sonar Model (GSM). CASS performs signal excess calculations.
- The GRAB model is a subset of the CASS model and its main function is to compute eigenrays and propagation loss as inputs in the CASS signal excess calculations.
Comprehensive Acoustic Simulation System/Gaussian Ray Bundle (CASS/GRAB)

- In the GRAB model, the travel time, source angle, target angle, and phase of the ray bundles are equal to those values for the classic ray path.

- The main difference between the GRAB model and a classic ray path is that the amplitude of the Gaussian ray bundles is global, affecting all depths to some degree whereas classic ray path amplitudes are local. GRAB calculates amplitude globally by distributing the amplitudes according to the Gaussian equation

\[
\Psi_v = \frac{\beta_{v,0} \Gamma_v^2}{\sqrt{2\pi} \sigma_v p_{r,v} r} \exp \left\{ -0.5 \left[ \frac{(z - z_v)}{\sigma_v} \right]^2 \right\}
\]
Mine Hunting Sonar

- Generic VHF forward looking
- CASS/GRAB input file for MIW with signal excess output
- Generic bottom moored mine
AN/SQQ-32 Mine Hunting Sonar System

- The CASS/GRAB Acoustic model input file used in this study simulates a VHF forward looking sonar, similar to the Acoustic Performance of the AN/SQQ-32.
- The AN/SQQ-32 is the key mine hunting component of the U.S. Navy's Mine Hunting and Countermeasure ships.
Detection Sonar and Classification Sonar Assembly

AN/SQQ-32 Pictorial Description

The AN/SQQ-32 is a critical part of the MCM/MHC Combat System. It provides long range mine detection, classification, and marking for subsequent sweeping/destruction.

Detection Sonar Assembly

Detection and Classification Cabinets

Operator's Display, Control, and Detection Panels

Deployment/Recovery Subsystem

Long Range Detection

Long Range Classification by Imaging
Input Parameters

- Bottom depth
- Target depth
- Transducer depth
- Wind speed
- Bottom type grain size index
- Frequency min/max
- Self noise
- Source level
- Pulse length
- Target strength/depth
- Transmitter tilt angle
- Surface scattering/reflection model
- Bottom scattering/reflection model
## Bottom Type Geoacoustic Properties

| Bottom Composition | Grain Size | Long Name          | Density | Sound Speed Ratio | Wave Number Ratio | Volume Parameter | Spectral Exponent | Spectral Parameter |
|--------------------|------------|--------------------|---------|-------------------|-------------------|------------------|-------------------|-------------------|--------------------|
| BOULDER            | -9.0       | ROUGH ROCK         | 2.500   | 2.5000            | 0.01374           | 0.0020           | 3.25             | 0.206930          |
| ROCK               | -7.0       | ROCK               | 2.500   | 2.5000            | 0.01374           | 0.0020           | 3.25             | 0.18620           |

Yellow Sea Bottom Sediment Chart

- Bottom Sediment types can vary greatly over a small area
  1. Mud
  2. Sand
  3. Gravel
  4. Rock
AN/SQQ-32 Employment

- Variable depth
  high frequency
  sonar system

- Sonar can be placed at various positions in the water column to optimize the detection of either moored or bottom mines.
Two Depths of Transducer

- Shallow Transducer: 17 ft (5.18 m)
- Deep Transducer (25 m)
- Water depth: 30 m
Uncertainty

- Tilt angles + 4° to − 12°
- Wind 5 – 25 knots
- Coarse sand to silt bottoms
Shallow Transducer

Acoustic Uncertainty Due to Wind and Bottom Uncertainty for Shallow Transducer (Range = 1200 m)
Acoustic Uncertainty Due to Wind and Bottom Uncertainty for Deep Transducer
(Range = 1200 m)
Difference Between Deep and Shallow Transducers (Range = 1200 m)
Conclusions

- Bottom type and wind variability are important for sandy silt detections.

- Acoustic uncertainty due to bottom type and wind data variability is on the order of a few decibels.

- Deep transducers provide higher signal excess for most detectable cases.
Recommendations

- Sensor improvements of a few decibels are significant for detection.

- Employment of sensors deeper aids bottom moored mine detection.
