## Outline

#### **Problem**

- Should simultaneously focus on both numerical and statistical accuracy.
  - Statistical accuracy: How well do the data capture the problem we want to solve?
  - Numerical accuracy: How quickly can we can compute an estimator to (insert number) of digits?

#### **Contributions**

We make a small contribution in this direction using proximal methods.

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● ● ●

We provide theoretical support for early stopping of scaled proximal methods.

- We have a parametric family of densities  $\{p(\cdot|\theta): \theta \in \Theta \subseteq \mathbb{R}^d\}.$
- Observe *n* independent copies X<sub>1</sub>, ..., X<sub>n</sub> of a random vector X ~ p(·|θ<sub>0</sub>).

▲□▶▲□▶▲≡▶▲≡▶ ≡ めぬぐ

• Do not know  $\theta_0$  and want to use  $X_1, ..., X_n$  to estimate it.

- We have a parametric family of densities  $\{p(\cdot|\theta): \theta \in \Theta \subseteq \mathbb{R}^d\}.$
- Observe n independent copies X<sub>1</sub>,..., X<sub>n</sub> of a random vector X ~ p(·|θ<sub>0</sub>).
- Do not know  $\theta_0$  and want to use  $X_1, ..., X_n$  to estimate it.

#### Theorem (Cramer-Rao Bound)

Assume that the Fisher Information exists.

$$I_{ heta_0} := \operatorname{Var}\left[ rac{\partial}{\partial heta} \log p(X| heta) \Big|_{ heta_0} 
ight]$$

Then any unbiased estimator  $\hat{\theta}$  of  $\theta_0$  satisfies

$$\operatorname{Var}\left[\hat{ heta}
ight] \succeq (nl_{ heta_0})^{-1}.$$

#### We define the Maximum Likelihood Estimator as

$$\hat{ heta}_{MLE} \in \operatorname{argmax}_{ heta \in \Theta} rac{1}{n} \sum_{i=1}^n \log p(X_i | heta).$$

#### We define the Maximum Likelihood Estimator as

$$\hat{ heta}_{MLE} \in \operatorname{argmin}_{ heta \in \Theta} - rac{1}{n} \sum_{i=1}^{n} \log p(X_i | heta).$$

#### We define the Maximum Likelihood Estimator as

 $\hat{\theta}_{MLE} \in \operatorname{argmin}_{\theta \in \Theta} F_n(\theta).$

where  $\rightarrow^{\mathcal{D}}$  denotes convergence in distribution.

#### We define the Maximum Likelihood Estimator as

 $\hat{\theta}_{MLE} \in \operatorname{argmin}_{\theta \in \Theta} F_n(\theta).$ 

#### Theorem (Fisher 1920s, Cramer 1946)

As the sample size  $n \to \infty$ , the maximum likelihood estimator is unbiased. Its variance matches the Cramer-Rao bound. More precisely,

$$\hat{ heta}_{\textit{MLE}} 
ightarrow^{\mathcal{D}} N( heta_0, (\textit{nl}_{ heta_0})^{-1})$$

where  $\rightarrow^{\mathcal{D}}$  denotes convergence in distribution.

We can rewrite the conclusion of the theorem

$$\sqrt{n}(\hat{\theta}_{MLE} - \theta_0) \rightarrow^{\mathcal{D}} N(0, I_{\theta_0}^{-1})$$

"The justification through asymptotics appears to be the only general justification of the method of maximum likelihood" - A. W. van der Vaart, *Asymptotic Statistics*.

- ▶ In "perfect data" regime, MLE has strong supporting theory.
- But these results were developed in the 1920s and 1940s!
- No computers  $\Rightarrow$  limited ability to *compute* MLE.
- How was a respectable statistician supposed to use this insight?

Lucien Le Cam (1924-2000)

<ロト <回ト < 三ト < 三ト = 三

## **One Step Estimators**

#### Theorem (Le Cam, 1956)

• Let  $\tilde{\theta}_{init}$  be an initial estimator of  $\theta_0$ , such that\*

$$\sqrt{n} \|\tilde{\theta}_{init} - \theta_0\| < M$$

for some M and n large enough.

Some mild regularity conditions hold.

Then performing a single Newton step on the objective function  $F_n$ , from starting point  $\tilde{\theta}_{init}$ , yields an estimator  $\hat{\theta}_{ose}$  which is asymptotically equivalent to  $\hat{\theta}_{MLE}$ .

This estimator

$$\hat{\theta}_{ose} := \tilde{ heta}_{init} - 
abla^2 F_n(\tilde{ heta}_{init})^{-1} 
abla F(\tilde{ heta}_{init})$$

is called the one step estimator.

## With Great Power...

- Starting within  $M \cdot n^{-1/2}$  of  $\hat{\theta}_{MLE}$ , for some constant M satisfies the condition on  $\tilde{\theta}_{init}$  in the theorem.
- ► This gives us "wiggle room" in the optimization of n<sup>-1/2</sup>, where n is the sample size.
- One step of Newton's method is sufficient for an asymptotically optimal estimator (unbiased with variance equal to Cramer-Rao).

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● ● ●

#### With Great Power...

- Starting within  $M \cdot n^{-1/2}$  of  $\hat{\theta}_{MLE}$ , for some constant M satisfies the condition on  $\tilde{\theta}_{init}$  in the theorem.
- This gives us "wiggle room" in the optimization of n<sup>-1/2</sup>, where n is the sample size.
- One step of Newton's method is sufficient for an asymptotically optimal estimator (unbiased with variance equal to Cramer-Rao).

In practice this gave statisticians license to optimize poorly.

- 1. Choose starting point
- 2. Run a few iterations of Newton's method (by hand!?)
- 3. Cite Le Cam's theory suggesting this is good enough.

You may want to scale this beyond Newton's method.

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三三 - のへぐ

Can we use gradient descent in Le Cam's theory?

You may want to scale this beyond Newton's method.

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三三 - のへぐ

Can we use gradient descent in Le Cam's theory?

Answer: No.

We estimate the population mean from multivariate normal observations

$$X \sim N\left( \left( egin{array}{c} 0 \\ 0 \end{array} 
ight), \left( egin{array}{c} 100 & 0 \\ 0 & 1 \end{array} 
ight) 
ight).$$

・ロト ・西ト ・ヨト ・ヨー うへぐ

Take starting point 
$$ilde{ heta} \sim U\left([-n^{-1/2},0] imes [-n^{-1/2},0]
ight)$$

The one step gradient descent estimator is biased.

Independent of n, this estimator underestimates the first coordinate of the mean

 ・

1. 
$$\phi_k = \theta_k - \gamma_k \nabla F(\theta_k)$$
  
2.  $\theta_{k+1} \in \operatorname{argmin}_{\theta \in \Theta} G(\theta) + \frac{1}{2\gamma_k} \|\theta - \phi_k\|_2^2$ .

$$\min_{\theta\in\Theta}F(\theta)+G(\theta)$$

is often solved with the following, called proximal gradient descent Initiate  $\theta_0$  and iterate the following for appropriate step lengths  $\gamma_k$ .

1. 
$$\phi_k = \theta_k - \gamma_k \nabla F(\theta_k)$$
  
2.  $\theta_{k+1} \in \operatorname{argmin}_{\theta \in \Theta} G(\theta) + \frac{1}{2\gamma_k} \|\theta - \phi_k\|_2^2$ .

The proximal operator of G with parameter  $\gamma$  is

$$\operatorname{prox}_{G,\gamma}(y) = \operatorname{argmin}_{\theta \in \Theta} G(\theta) + \frac{1}{2\gamma} \|\theta - y\|_2^2.$$

$$\min_{\theta \in \Theta} F(\theta) + G(\theta)$$

is often solved with the following, called proximal gradient descent Initiate  $\theta_0$  and iterate the following for appropriate step lengths  $\gamma_k$ .

1. 
$$\phi_k = \theta_k - \gamma_k \nabla F(\theta_k)$$
  
2.  $\theta_{k+1} \in \operatorname{argmin}_{\theta \in \Theta} G(\theta) + \frac{1}{2\gamma_k} \|\theta - \phi_k\|_2^2$ 

The proximal operator of G with parameter  $\gamma$  is

$$\operatorname{prox}_{G,\gamma}(y) = \operatorname{argmin}_{\theta \in \Theta} G(\theta) + \frac{1}{2\gamma} \|\theta - y\|_2^2.$$

So the proximal gradient method consists of applying a gradient step (in F) and proximal step (in G) for each iteration.

## Scaled Proximal Gradient

Proximal gradient has an extension called *Scaled Proximal Gradient* for scaling matrices  $C_k \succ 0$ .

Prox Gradient Iterate the following:

1. Gradient Step

$$\phi_k = \theta_k - \gamma_k \nabla F(\theta_k)$$

2. Proximal Step

Prox Newton Iterate the following:

1. Newton Step

$$\phi_k = \theta_k - C_k^{-1} \nabla F(\theta_k)$$

2. Scaled Proximal Step

 $\begin{array}{l} \theta_{k+1} \in \mathop{\mathrm{argmin}}_{\theta \in \Theta} & \theta_{k+1} \in \mathop{\mathrm{argmin}}_{\theta \in \Theta} \\ G(\theta) + \frac{1}{2\gamma_k} \|\theta - \phi_k\|_2^2 & G(\theta) + \frac{1}{2} \|\theta - \phi_k\|_{\mathcal{C}_k}^2 \end{array}$ 

Recall that  $||y||_C^2 = y^T C y$  is the weighted euclidean norm

## Prox Gradient vs Scaled Prox Gradient

Prox Gradient Scaled Prox Gradient

- (Often) Closed form prox
- Linear convergence rate

- Rarely closed form prox
- Superlinear convergence rate

Scaled Prox Gradient is used by reputable packages such as glmnet, newglmnet, QUIC (QUadratic Inverse Covariance estimation).

## Main Contribution

#### Theorem (Bassett & Deride, '21)

Assume we have the composite model, and form estimator

$$\hat{\theta}_M = \operatorname{argmin}_{\theta \in \Theta} F_n(\theta) + G(\theta)$$

where  $F_n$  is negative log likelihood and G is a regularizer. If

- $\tilde{\theta}_{init}$  is an initial estimator within\*  $M \cdot n^{-1/2}$  of  $\hat{\theta}_M$ .
- G(θ) is convex.
- The scaling  $C_n$  is  $\succ 0$  and  $C_n^{-1}I_{\theta_0} \rightarrow^{n \rightarrow \infty} I$ .

Some mild regularity conditions hold.

Then  $\hat{\theta}$ , the one-step estimator with scaled proximal gradient, is asymptotically equivalent to  $\hat{\theta}_M$ .

That is, 
$$\sqrt{n}(\hat{ heta} - \hat{ heta}_M) 
ightarrow 0$$
 in probability.

## When solving penalized log-likelihood with scaled proximal gradient,

#### Numerical error should scale like $n^{-1/2}$

in order to respect the statistical nature of the problem

#### Interpretation as a Smoother

The (scaled) proximal operator has a well known interpretation as a smoother, via the infimal convolution of epigraphs.

Therefore our results provide theoretical justification for smoothing of a statistical objective using infimal convolution.

## Example: Cauchy Likelihood with Laplacian Prior

(c) n=700

(b) n=400

Sac

#### Proximal Descent and Scaled Proximal Descent

We have a similar result for scaled proximal descent, where we have the estimator

$$\hat{\theta}_M = \operatorname{argmin}_{\theta \in \Theta} F_n(\theta)$$

and we iterate the scaled proximal operator:

$$heta_{n+1} \in \operatorname{argmin}_{\theta \in \Theta} F_n( heta) + rac{1}{2} \| heta - heta_k \|_{C_n}^2$$

Theorem (Bassett & Deride, '21) If  $C_n \to 0$ ,  $\|\tilde{\theta}_{init} - \hat{\theta}_M\| \le M/\sqrt{n}$ , and the scaled prox is Lipschitz continuous, then  $\operatorname{argmin}_{\theta \in \Theta} F_n(\theta) + \frac{1}{2} \|\theta - \tilde{\theta}_{init}\|_{C_n}^2$  is asymptotically equivalent to  $\hat{\theta}_M$ .

## Summary

- Le Cam worked on early stopping results for Newton's method applied to MLE.
- We extend this insight to penalized and constrained problems by considering Scaled Proximal Methods.
- Scaled Proximal Methods work similarly to Newton–a one-step estimator from a starting point within n<sup>-1/2</sup> of the minimum behaves like the minimum.
- Applies to many problems where we want to build structured estimates from data.
